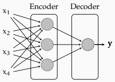
Encoder–decoder models

- All machine learning methods can be seen performing two tasks:
  - *encoding* the input into a useful representation
  - *decoding* the representation into the output
- In more traditional methods, encoding is 'manual', or external to the learning algorithm
- Modern deep learning methods include the encoder: they learn to build (multiple layers/hierarchies of) useful input representations

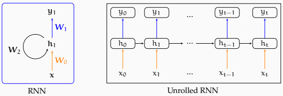
A simple encoder–decoder network

we can view any neural network as two parts



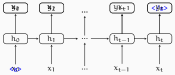
- The encoder encodes the input in hidden representations
- Decoder 'decodes' the encoded input to the output
- In computational linguistics, many tasks require encoding and decoding *sequences*

Recap: RNNs



Uses of RNNs

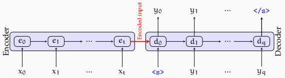
Many-to-many with a delay (e.g., machine translation, summarization, question answering, ...)



RNN problems, solutions, variations

- (Unfolded) RNNs can be deep (based on the length of the input), this results in
  - exploding gradients – solution: gradient clipping
  - vanishing gradients – solution: gated RNNs (to some extent)
- More generally, keeping relevant information over longer sequences are difficult – solution: attention (this lecture)
- RNNs condition the prediction in only one direction – solution: bidirectional RNNs
- It is also common to stack multiple layers of RNNs
- RNNs are inherently sequential, this prevents parallel processing

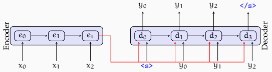
Sequence-to-sequence RNNs (seq2seq)



- Note that the decoder is a RNN language model
- Both input and output can be arbitrary length
- All information about the input is coded in a single encoding vector

Sequence-to-sequence RNNs (seq2seq)

a simple improvement

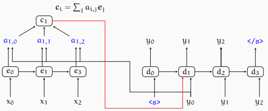


- Instead of passing the encoder output (context vector) to the first decoder state, pass it to all time steps
- Helps decoder to not to forget the encoder state, but early words in the encoder may not be represented well in the context vector

Attention: the general idea

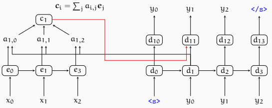
- A naive solution could be passing all intermediate steps of the encoder to the decoder states (e.g., concatenate or average)
- However, in many problems, a part of the input is relevant for predicting the current output
- A common solution to the problem is *attention* mechanism
- Attention is about focusing into the relevant parts of the input
- In sequence-to-sequence problems, this corresponds to alignment

Sequence-to-sequence RNN with attention



Sequence-to-sequence RNN with attention

another variation



Calculating attention weights

- The context vector is the sum of the encoder states, weighted by attention, $a_{i,j}$

$$\mathbf{c}_i = \sum_j a_{i,j} \mathbf{e}_j$$

- Typically the weights are normalized through *softmax* the result is an attention distribution

$$a_{i,j} = \frac{e^{f(\mathbf{d}_{i-1}, \mathbf{e}_j)}}{\sum_k e^{f(\mathbf{d}_{i-1}, \mathbf{e}_k)}}$$

- The attention function, $f(\cdot)$ computes the relevance of encoder state $\mathbf{e}_j$ to the decoder state $\mathbf{d}_i$

Some (common) attention functions

- Dot product:

$$f(\mathbf{d}_i, \mathbf{e}_j) = \mathbf{d}_i^T \mathbf{e}_j$$

- Generalized dot product:

$$f(\mathbf{d}_i, \mathbf{e}_j) = \mathbf{d}_i^T W_a \mathbf{e}_j$$

- Scaled dot product:

$$f(\mathbf{d}_i, \mathbf{e}_j) = \frac{\mathbf{d}_i^T \mathbf{e}_j}{\sqrt{k}}$$

- Additive attention:

$$f(\mathbf{d}_i, \mathbf{e}_j) = v^T \tanh(W_a d_i + U_a e_j)$$

Hard and soft attention

- The mechanism we described is called *soft attention*: The attention mechanism allows attending to more than one input in a weighted manner
- The case where the attention weights form a one-hot vector is called *hard attention*
- Soft attention is common, both because of its flexibility and ease of training (continuous / differentiable functions)

Attention and content addressable memory

- In the literature, attention mechanism is often explained as a form of content-addressable (or associative) memory: decoder state is used to query the encoder states

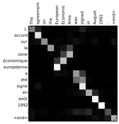
query key value

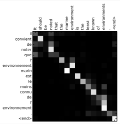
$$a_{i,j} = \frac{e^{f(\mathbf{d}_{i-1}, \mathbf{e}_j)}}{\sum_k e^{f(\mathbf{d}_{i-1}, \mathbf{e}_k)}} \qquad \mathbf{c}_i = \sum_j a_{i,j} \mathbf{e}_j$$

- In this setting, *key* and *value* are the same
- In case of hard attention, the mechanism is equivalent to associative arrays (maps)

Example attention weights

machine translation (en–fr)





Example attention weights

caption generation

A woman is throwing a frisbee in a park.

A dog is standing on a hardwood floor.

A stop sign is on a road with a mountain in the background.

A little girl sitting on a bed with a teddy bear.

A group of people sitting on a boat in the water.

A giraffe standing in a forest with trees in the background.

Example attention weights

caption generation

A large white bird standing in a forest.

A woman holding a clock in her hand.

A man wearing a hat and a hat on a skateboard.

A person is standing on a beach with a surfboard.

A woman is sitting at a table with a large pizza.

A man is talking on his cell phone while another man watches.

Summary

- Attention is a general mechanism to focus on certain parts of input
- It is also useful for generating 'explanations'
- Attention is the basic mechanism behind the current state of the art models (transformers)
- Reading: Jurafsky and Martin (2026, Chapter 8)

Next:

- Self attention and transformers architecture (Reading: Jurafsky and Martin (2026, Chapter 9))
